Art analysis of the classification from 2024

This has been written in 2025.

The main objective is to classify the publications by themes and sub-theme.

The work from 2024

It seems to work well. However there are two possible issues:

 There are not enough themes to cover all the possible scientific publications.

Let's consider only the publications that are related to the given themes.

• The classification is only made on the *abstract* of the publication, and not on the title or even the keywords that the *HAL* **API** could give for istance.

I think it could be good if we gave the title, the abstract and the retrieved keywords altogether to the classify_abstract_combined() function.

It will give the related *theme* if the publication is within the covered range of themes.

In fact, it may be necessary to replace the Flask API because:

```
WARNING: This is a development server. Do not use it in a production deployment. Use a production WSGI server instead.
```

So anyway, the current Flask API will have to be reworked. Here are some ideas:

- 1. **Use HTTP requests with** *Flask*. This is easiest way because it requires small changes, however this is not designed for that I suppose. In fact, the only good way to get a *Flask* server for production is to use *gunicorn*.
- Use Child Processes in Node.js. Here is a more detailed guide right here.
- 3. Use Websocket like Socketio. I don't want the websocket to require an authentication because it will be too hard to code. That's why the client must not have the right to communicate with the websocket. Only the server should do that. So for this method, the server classifies the publication and not the client.

For any of these methods, here is the generic plan on this picture:

Better $\it README$ file and $\it explanations$.

I had some issues to launch the *flask* app.

Here is a more detailed guide on how to use it for **python3.13**:

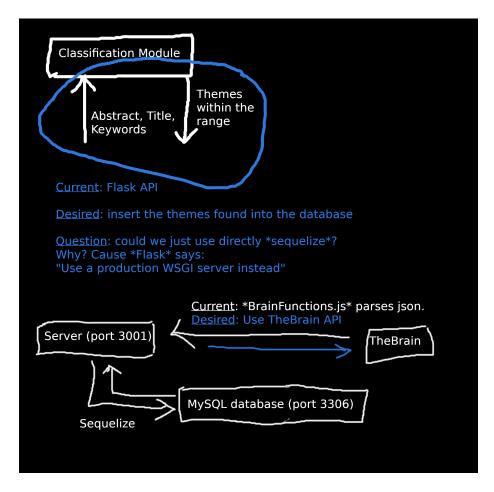

Figure 1: Classification Module

```
cd classification/code/
python3 -m venv .env_classification
source .env_classification/bin/activate
pip install -r requirements.txt
where the requirements.txt file is:
spacy==3.8.7
flask==3.1.1
nltk==3.9.1
scikit-learn==1.6.1
Then do:
python -m spacy download en_core_web_lg
./start_classification.sh
If there is the error port 5000 already used, just do:
ps aux | grep app.py
kill -9 <app.py pid>
```

My own thoughts about the idea

The solution is good, nothing to add, except there are not enough themes.

The different solutions that already exist.

It is possible to use a $Natural \ Language \ Processing$ to get better results. However, it is not that easy.

In fact, I just need to use **BERT** which is an $NLP \ model \ (+68M \ monthly \ downloads)$. It could be very powerful, more powerful than the current classification model.

But the current model from 2024 is good, I don't want to mess with it.
